

## Question 1

## Estimating all-pairs distances exactly

**Algorithm 1:** Monte Carlo Algorithm for exact distance

---

**Input:**  $G$ , partial distance matrix  $M$   
**Output:** complete distance matrix  $M$  with error probability  $< 1 - 1/n^2$   
 $D \leftarrow n \times n$  matrix to store distance  
**for**  $i \leftarrow 1$  **to**  $n$  **do**  
    **for**  $j \leftarrow 1$  **to**  $n$  **do**  
        **if**  $M[i][j] = \#$  **then**  
             $D[i][j] = \text{infinity}$   
        **else**  
             $D[i][j] = M[i][j]$   
        **end**  
    **end**  
**end**  
**for**  $k \leftarrow 1$  **to**  $K$  **do**  
     $w \leftarrow \text{Random vertex in } [1 : n]$   
     $dist = bfs(G, w)$   
    **for**  $i \leftarrow 1$  **to**  $n$  **do**  
        **for**  $j \leftarrow 1$  **to**  $n$  **do**  
             $D[i][j] = \min(D[i][j], dist[i] + dist[j])$   
        **end**  
    **end**  
**end**  
**return**  $M$

---

**Complexity analysis**

In above algorithm  $bfs(G, s)$  returns an array storing shortest distance of  $s$  to each vertex in  $G$ . Time complexity for  $bfs$  is  $O(n + m)$  ( $m$  = number of vertices in graph). In worst case there can be atmost  $\binom{n}{2}$  edges, i.e worst case complexity of  $bfs$  is  $O(n^2)$ . Time taken to update  $D$  in one iteration is also  $O(n^2)$ . Since outer loop runs for  $K$  times, total complexity is  $O(n^2 K)$ . In below analysis it is show that  $K = O(\log n)$ , hence complexity of above algorithm is  $O(n^2) \log n$ .

**Error Analysis**

Error will occur if there are  $\geq 1$  entries in  $D$  which are not equal shortest path distance.

$$P(\text{error}) = P(M[1][1] \text{ wrong} \cup M[1][2] \text{ wrong} \dots \cup M[n][n] \text{ wrong})$$

Applying Boole's inequality we get:

$$P(\text{error}) \leq n^2 * P(M[i][j] \text{ wrong}) \quad (\text{distance between } i, j > n/100)$$

Note that there is  $\leq$  sign in above line since the points for which distance  $\leq n/100$  matrix  $M$  stores correct value (since the value is taken directly from partial distance matrix).

 **$M[i][j]$  computed wrong**

We know that distance between  $i, j$  is greater than  $n/100$ , i.e number of nodes between shortest path from  $i$  to  $j$  is  $\geq n/100$ . So now consider first iteration of first loop.

Note that  $w$  is chosen randomly, hence the probability that  $w$  belongs to shortest path from  $i$  to  $j$  is  $\geq \frac{n/100}{n} = \frac{1}{100}$ .

If  $w$  belong to shortest path then  $D[i][j]$  will be updated correctly and will contain shortest path distance (since we are doing  $bfs$  from  $w$ , we get shortest path value from  $w \rightarrow i, w \rightarrow j$ ,  $M[i][j]$  is simple the sum

of these 2 values).

Probability that  $D[i][j]$  is wrong ( $P(\delta)$ )  $\leq \frac{99}{100}$

Probability that  $D[i][j]$  is wrong even after  $K$  iteration  $\leq P(\delta)^K = \left(\frac{99}{100}\right)^K$

Using this value in above equation we get

$$\begin{aligned} P(\text{error}) &\leq n^2 P(\delta) \\ &\leq n^2 \left(\frac{99}{100}\right)^K \end{aligned}$$

We want that error probability is  $\leq 1/n^2$ , or

$$\begin{aligned} P(\text{error}) &\leq \frac{1}{n^2} \\ n^2 \left(\frac{99}{100}\right)^K &\leq \frac{1}{n^2} \\ \left(\frac{99}{100}\right)^K &\leq \frac{1}{n^4} \\ K \log \left(\frac{100}{99}\right) &\geq 4 \log n \\ K &\geq \frac{4}{\log(100/99)} \log n \end{aligned}$$

Taking  $K = 400 \log n$  we get that all entries of the distance matrix are correct with probability exceeding  $1 - 1/n^2$ .

## Question 2

## Rumour Spreading

We will partition the experiment into following three stages. Let  $X$  is the number of persons knowing the rumour at any time. The stages are -

1.  $X < c \log n$
2.  $c \log n < X < \frac{n}{2}$
3.  $\frac{n}{2} < X < n$

Expected no. of days to spread the rumour is the sum of expected no. of days spent in each of these stages.

(1) Expected no. days spent in stage 1 -

Let  $p$  is the probability that no new person comes to know about the rumour at the end of some day. Let  $k$  be the no. of persons knowing the rumour at the start of the day.

Thus,

$$p = \left( \frac{k-1}{n-1} \right)^k \approx \left( \frac{k}{n} \right)^k$$

For  $1 \leq k < \frac{n}{2}$ ,  $p \leq \left( \frac{1}{2} \right)^k \leq \frac{1}{2}$

So, expected no. of days for at least one person to know the rumour is  $\frac{1}{1-p} \leq 2$ .

Thus the expected no. of days for  $c \log n$  persons to know the rumour is less than or equal to  $2c \log n$ .

Expected no. of days spent in first stage,

$$N_1 = 2c \log n$$

(2) Expected no. days spent in stage 2 -

Let the label of the person called by  $i^{th}$  person be  $x_i$ . Clearly,  $x_1, x_2, \dots, x_k$  are independent.

Consider  $f(x_1, x_2, \dots, x_k)$  : No. of persons not knowing the rumor at the end of day, if the no. of persons not knowing the rumor at the beginning of the day was  $r$ .

By linearity of expectation and since  $n - \log n < r$ ,

$$E[f] = r \left( \frac{n-1}{n} \right)^{n-r} \leq \frac{r}{c}, c > 1$$

Clearly,  $|f(A) - f(A_0)| \leq 1$  for all  $A, A_0$  that differ only at the  $i^{th}$  coordinate.

Thus,  $f$  satisfies Lipschitz condition with parameters  $c_1, c_2, \dots, c_k$ ,  $c_i = 1$ .

Take  $p$  such that  $1 < p < c$ , call a day good if  $f < \frac{r}{p}$  at the end of the day. Expected no. of good days required for this stage is  $O(\log n)$

$$P[\text{day is bad}] = P \left[ f \geq \frac{r}{p} \right]$$

$$P[\text{day is bad}] = P \left[ f - \frac{r}{c} \geq \frac{r}{p} - \frac{r}{c} \right]$$

$$P[\text{day is bad}] \leq P \left[ |f - E[f]| \geq \frac{ru}{c} \right], u > 0$$

Using the method of bounded difference,

$$P[\text{day is bad}] \leq \exp \left( \frac{-u^2 r^2}{2c^2 \sum c_i^2} \right)$$

Since  $r < \frac{n}{2}$

$$P[\text{day is bad}] < \exp \left( \frac{-u^2 n^2}{8c^2 n} \right)$$

$$P[\text{day is bad}] \leq \exp(-kn)$$

Thus probability that a day is bad is inverse exponential in  $n$  and hence the expected no. of days spent in second stage =  $O(\log n)$ .

(3) Expected no. days spent in stage 3 -

Let  $k$  be the no. of persons knowing the rumour at the start of the day and let  $r$  be the no. of persons not knowing the rumour at the start of the day ( $r = n - k$ ).

Let  $p_i$  be the probability that  $i^{th}$  person does not know the rumour at the end of the day.

$$p_i = \left( \frac{n-1}{n} \right)^k$$

Since  $k > \frac{n}{2}$ ,

$$p_i \leq \left( 1 - \frac{1}{n} \right)^{\frac{n}{2}} \approx \frac{1}{\sqrt{e}}$$

Let  $R_i$  be the random variable which takes value 1 if the  $i^{th}$  person does not know the rumour at the end of the day and 0 otherwise.

Let  $R$  be the no. of persons not knowing the rumour at the end of the day.

Now by linearity of expectation,

$$E[R] = \sum_{i=1}^r E[R_i]$$

$$E[R] = \sum_{i=1}^r p_i + 0(1 - p_i)$$

$$E[R] \leq \frac{r}{\sqrt{e}}$$

Define a day to be good if the no. of persons not knowing the rumour reduces by more than  $\frac{1}{\sqrt{2}}$  from the start of the day.

Thus the expected no. of good days required for spreading the rumour to  $n$  people is  $2 \log n$ .

Let  $p$  be the probability that a day is bad,

$$p = P \left[ R \geq \frac{r}{\sqrt{2}} \right]$$

Using Markov's inequality,

$$p \leq \frac{\sqrt{2}E[R]}{r}$$

$$p \leq \frac{\sqrt{2}}{\sqrt{e}} \leq \frac{7}{8}$$

and so probability of a day being good is at least  $\frac{1}{8}$ .

Thus the Expected no. of days spent in third stage,

$$N_3 = 16 \log n = q \log n$$

## Question 3

## Approximate Ham-Sandwich Cut

**Algorithm 1:** Las-Vegas Algorithm for  $(1 + 1/2)$ -approximate ham-sandwich cut of  $P$ **Input:** set  $P$  of  $2n$  points,  $n$  red and  $n$  blue**Output:**  $(1 + 1/2)$ -approximate ham-sandwich cut of  $P$ **repeat**     $K \leftarrow$  random sample containing  $k/2$  red, and  $k/2$  blue points.     $L = \text{ExactHamCut}(K, k)$         */\* count red points that lie on either side, with reference to origin. \*/*     $c\_red\_l \leftarrow 0$      $c\_red\_r \leftarrow 0$     **for**  $i \leftarrow 1$  **to**  $n$  **do**        **if**  $P[i], (0, 0)$  *lie on same side of*  $L$  **then**             $c\_red\_l \leftarrow c\_red\_l + 1$         **else**             $c\_red\_r \leftarrow c\_red\_r + 1$     **end**    **if**  $n/4 \leq c\_red\_l \leq 3n/4$  **&&**  $n/4 \leq c\_red\_r \leq 3n/4$  **then**         $red \leftarrow \text{True}$     **else**         $red \leftarrow \text{False}$         */\* count blue points that lie on either side, with reference to origin. \*/*     $c\_blue\_l \leftarrow 0$      $c\_blue\_r \leftarrow 0$     **for**  $i \leftarrow n + 1$  **to**  $2n$  **do**        **if**  $P[i], (0, 0)$  *lie on same side of*  $L$  **then**             $c\_blue\_l \leftarrow c\_blue\_l + 1$         **else**             $c\_blue\_r \leftarrow c\_blue\_r + 1$     **end**    **if**  $n/4 \leq c\_blue\_l \leq 3n/4$  **&&**  $n/4 \leq c\_blue\_r \leq 3n/4$  **then**         $blue \leftarrow \text{True}$     **else**         $blue \leftarrow \text{False}$     **if**  $blue$  **&&**  $red$  **then**        **return**  $L$ **until**  $\text{True}$ ;

**Algorithm 1:** ExactHamCut

---

**Input:** set  $X$  of  $m$  points,  $m/2$  blue,  $m/2$  red  
**Output:** Exact Ham-Sandwich cut for  $X, m$   
 $R \leftarrow$  set of red points ( $|R| = m/2$ )  
 $B \leftarrow$  blue points  
**for**  $i \leftarrow 1$  **to**  $m - 1$  **do**  
  **for**  $j \leftarrow i + 1$  **to**  $m$  **do**  
     $L \leftarrow$  line joining  $X[i], X[j]$   
      /\* Check if  $L$  is an exact ham-sandwich cut. \*/  
      /\* count red points that lie on either side, with reference to origin. \*/

       $c\_red\_r \leftarrow 0$   
      **for**  $i \leftarrow 1$  **to**  $m/2$  **do**  
        **if**  $R[i], (0, 0)$  lie on same side of  $L$  **then**  
           $c\_red\_l \leftarrow c\_red\_l + 1$   
        **else**  
           $c\_red\_r \leftarrow c\_red\_r + 1$   
      **end**  
      **if**  $c\_red\_l \leq m/4 \ \&\& \ c\_red\_r \leq m/4$  **then**  
         $red \leftarrow \text{True}$   
      **else**  
         $red \leftarrow \text{False}$   
      /\* count blue points that lie on either side, with reference to origin. \*/  
       $c\_blue\_l \leftarrow 0$   
       $c\_blue\_r \leftarrow 0$   
      **for**  $i \leftarrow 1$  **to**  $m/2$  **do**  
        **if**  $B[i], (0, 0)$  lie on same side of  $L$  **then**  
           $c\_blue\_l \leftarrow c\_blue\_l + 1$   
        **else**  
           $c\_blue\_r \leftarrow c\_blue\_r + 1$   
      **end**  
      **if**  $c\_blue\_l \leq m/4 \ \&\& \ c\_blue\_r \leq m/4$  **then**  
         $blue \leftarrow \text{True}$   
      **else**  
         $blue \leftarrow \text{False}$   
      **if**  $blue \ \&\& \ red$  **then**  
        **return**  $L$   
    **end**  
  **end**  
**end**

---

**Overview**

We take random sample of size  $k$ , containing equal number of red and blue points, compute their exact ham sandwich cut, and check if this cut is an approximate ham sandwich cut for global set  $P$  as well. If yes then we report it, else repeat. Since there are only  $\binom{k}{2}$  possible cuts, for deterministic algorithm we just check all the possible pairs in  $O(k)$ .

**Complexity analysis**

Time complexity of exact ham-sandwich cut above is  $O(k^3)$  (since we need to check  $\binom{k}{2}$  lines). From below analysis we know that for  $k = 40 \log n$ , the probability that algorithm will not terminate in 1 iteration is  $\leq \frac{1}{n^4}$ . Complexity of Las Vegas algorithm for approximate ham cut above is in fact a geometric random

variable with success probability  $\geq 1 - \frac{1}{n^4}$ . Expected number of iteration ( $E(t)$ ) is given by:

$$\begin{aligned} E(t) &= \frac{1}{\text{Success probability}} \\ &\leq \frac{1}{1 - \frac{1}{n^4}} \\ &\leq \frac{n^4}{n^4 - 1} \\ \text{or } E(t) &= O(1) \end{aligned}$$

In one iteration we call ExactHamCut ( $O(k^3)$ ) for a set of points of size  $k$ , and then we check for all points ( $O(n)$ ). So overall complexity of one iteration is  $O(k^3 + n) = O(\log^3 n + n)$ . Since expected number of iterations is  $O(1)$ , expected total complexity of algorithm is given by:  $O(\log^3 n + n) = O(n)$ .

### Error Analysis:

Error will occur when more than  $\frac{3n}{4}$  red or  $\frac{3n}{4}$  blue points lie on either side of the line which is the exact ham-sandwich cut of  $k$  points.

Without loss of generality assume that more than  $\frac{3n}{4}$  red points lie on one side of the line.

This means that when selecting  $\frac{k}{2}$  red points uniformly randomly,  $\frac{k}{4}$  red points got sampled from a cluster of less than  $\frac{n}{4}$  points and the other  $\frac{k}{4}$  red points were sampled from the remaining points on the other side of the line.

So, we know that less than  $\frac{n}{4}$  red points are on one side, let there be  $\frac{n}{4} - x$  points, error event is the union of  $\binom{\frac{n}{4} - x}{\frac{k}{4}}$  combinations for all  $x \in \{1, \dots, \frac{n}{4} - \frac{k}{4}\}$  which is same as the probability of getting more than  $\frac{k}{4}$  tails in  $\frac{k}{2}$  tosses of a biased coin having probability of head as  $\frac{3}{4}$ .

Thus,

$$P[\text{error}] \leq 2 * P[\text{more than } \frac{k}{4} \text{ tails occur in } \frac{k}{2} \text{ tosses}]$$

Taking into account the blue points, we have multiplied by 2.

$$P[\text{error}] \leq 2 * \sum_{i=\frac{k}{4}}^{\frac{k}{2}} \binom{\frac{k}{2}}{i} \frac{1}{4}^i \frac{3}{4}^{\frac{k}{2}-i}$$

$$P[\text{error}] \leq 2 * \binom{\frac{k}{2}}{\frac{k}{4}} \frac{3}{4}^{\frac{k}{2}} \sum_{i=\frac{k}{4}}^{\frac{k}{2}} \frac{1}{3}^i$$

$$P[\text{error}] \leq 2 * \binom{\frac{k}{2}}{\frac{k}{4}} \frac{3}{4}^{\frac{k}{2}} \frac{1}{3}^{\frac{k}{4}} \frac{3}{2}$$

$$P[\text{error}] \leq 3 * 4^{\frac{k}{4}} \frac{3}{4}^{\frac{k}{2}} \frac{1}{3}^{\frac{k}{4}}$$

$$P[\text{error}] \leq 3 * \frac{3}{4}^{\frac{k}{4}}$$

$$P[\text{error}] \leq \frac{1}{2}^{\frac{k}{10}}, k > 10$$

To get an error probability less than  $n^{-4}$  take  $k = 40 \log n$ .
